Ratio calculator method

Ratio calculator is a unique tool wherein harmonic vibration of important low price are matched with unique price/time ratio. When ratio matches with mentioned low/high price, corresponding price is marked as important vibration of the said point. Surprisingly, it is found that scrip vibrates to such ratios.

Let us have clear idea about the concept through following example.. Suppose Rs 100/- is important low of the scrip then following will be one of the possibilities.....

<u>Price</u>	<u>Time</u>	<u>P/T ratio</u>
100	1	100
101	2	50.5
102	3	34
103	4	25.75
104	5	20.8
105	6	17.5
106	7	15.14286
107	8	13.375
108	9	12
109	10	10.9
110	11	10

Corresponding price to the harmonic number

It is found that scrip actually takes resistance and support to the corresponding matched harmonic ratio. We may need to go through thousands of iterations to match these unique ratios. In this tool we use different octave ratios, musical vibration ratios, geometrical ratios, harmonic ratios as well as inverse of all these ratios. Now you can see, it becomes

difficult for human brain to match thousands of permutation and combinations with hundreds of different ratios. This job is done by a click of mouse through this unique tool. Our job is to finalise which scrip is obeying which set of ratios by trial and error, once we know the set we know the unique characteristic of that scrip, which the scrip follows in future. Following is the screen shot of ratio calculator tool in Fortune Plus software.

In this method we apply different ratios to the original number. Consider Rs 10 is our low, and when we select ratios under green and red colour, we consider following numbers as our input,

Ratios	Actual input	Ratio reciprocal	Actual input	Fibonacci ratios	Actual input	Fibonacci ratios reciprocal	Actual input
1/10th	10			1.272	12.72	1.272	7.861
1/8th	12.5			1.618	16.18	1.618	6.18
1/4th	25			1.902	19.02	1.902	5.257
3/8th	37.5	3/8th	26.66	2.058	20.58	2.058	4.859
1/2th	50			2.618	26.18	2.618	3.819
5/8th	62.5			3.33	33.3	3.33	3
3/4th	75			4.236	42.36	4.236	2.36
7/8th	87.5	7/8th	11.428	5.388	53.88	5.388	1.855
1/3rd	33.33	1/3rd	30	6.854	68.54	6.854	1.459
2/3rd	66.67	2/3rd	15				

Please check below mentioned example. We have taken trading day chart of Divi's Lab. We have selected green colour ratios initially from the top of Rs 1381.6. We have kept tolerance level to standard kept by software i.e 0.005. In checking downside we need to keep increment to -1 . We got 5 different ratios which matched with original number and lowest bottom is marked on 29th May 2017.

In second instance we have taken Rs 532.65 low marked on 29th May 2017 as our input. We got 5 matches and top one gave us a major top.

Fig 12.1 – Application ratio calcy on Divis Lab

With the help of ratio calculator we can get important reversal price points. We can check for swings and once we get retracements and reversal bar we can enter the trade either long or short depending the direction of the swing. Well we need to check lot many other confluence for actual trade entry.

We have applied ratio calculator on price, by taking price as input. We can use same technique by taking time as input. If we take time interval between any two important location as our input then we can get time cluster which can be important for change in price.

We will check this concept on Tatamtrdvr, we have considered 11th Nov 2010 to 24th Aug 2011 as important swing. Time difference in two locations is 197 days, remember here we are taking trading day chart, if we use calendar day chart results will be different.

Fig 12.1 – Application ratio calcy on Divis Lab

Check above chart we can see lot of time lines created by ratio calculator actually forming time resistance points.

Till now we have used price and time as input in ratio calculator independently. We can take both the inputs simultaneously and if we get cross section of price cluster and time cluster we will definitely get strongest resistance or support, since whenever price matches with time change will occur.
